17 **Highlights**

- 18 • Off-site economic costs of runoff and erosion were quantified through an analysis of public
19 expenditures for the last two decades.
- 20 • The total avoidance damages cost ranged from 375 to 485 M€.
- 21 • The total social damages cost reached 236 M€.
- 22 • The mean cost per capita was estimated to 9.1 and 21.6 € yr⁻¹ for the Eure and the Seine-
23 Maritime respectively.

24 **Abstract**

25 While soil erosion and runoff physical aspects are widely addressed in the literature, few
26 studies have focused on the economical dimension. However, it is essential to consider this dimension
27 to conduct appropriate land use management policies. Erosion and runoff are known to result into on-
28 site and off-site impacts. A fully exhaustive analysis of erosion and runoff economic costs may be

29 difficult and ambitious due to the availability of the data and a lack of actual knowledge. In this study,
30 we chose to analyze the main off-site economic costs induced by these processes in two specific areas
31 located in the northwestern European loess belt (Normandy, France). We quantified avoidance and
32 social damages over the last 25 years through a global and retrospective analysis of financial databases
33 provided by regional or local authorities (water agencies, departmental councils, reinsurance, drinking
34 water companies, transport infrastructures managers) and existing literature review. Our analysis
35 suggested that over that period, the total damages cost ranged from 611 to 721 M€. Off-site avoidance
36 damage costs accounted for almost 2/3 of the total expenditure. In the Seine-Maritime area, the mean
37 cost was evaluated to 21.6 € yr⁻¹ cap⁻¹ and to 9.1 € yr⁻¹ cap⁻¹ in the Eure area. Even if we tried to be as
38 exhaustive as possible some off-site economic costs remained unknown. It appeared that more
39 research is necessary for the scientific community to get a full picture of off-site economic costs
40 induced by erosion and runoff.

42 Erosion; runoff; off-site impacts; costs; damages; loess belt

43 **1 Introduction**

44 Soil erosion is recognized as one of the most pressing environmental problem of our time,
45 decreasing agricultural productivity, degrading ecosystem function, and amplifying hydrogeological
46 risks (UN FAO, 2019). Since several years, scientific studies have essentially focused on the physical
47 aspect of this phenomenon over the economic aspect. As reported by Panagos et al. (2018), a simple
48 Google Scholar search reported that only 0.4% of the publications relevant to soil erosion focus on the
49 economical dimension. However, soil erosion can generate multiple economic costs, which can be
50 divided into two main categories depending on the affected territories. Economic costs due to on-site
51 impacts that directly affect farmland through a loss of fertile topsoil and a consequent decrease of
52 productivity (de la Rosa et al., 2000; Bakker et al., 2004; Lal, 2010). Economic costs generated by off-
53 site impacts which can include in-stream problems of water quality and quantity, siltation of dams,

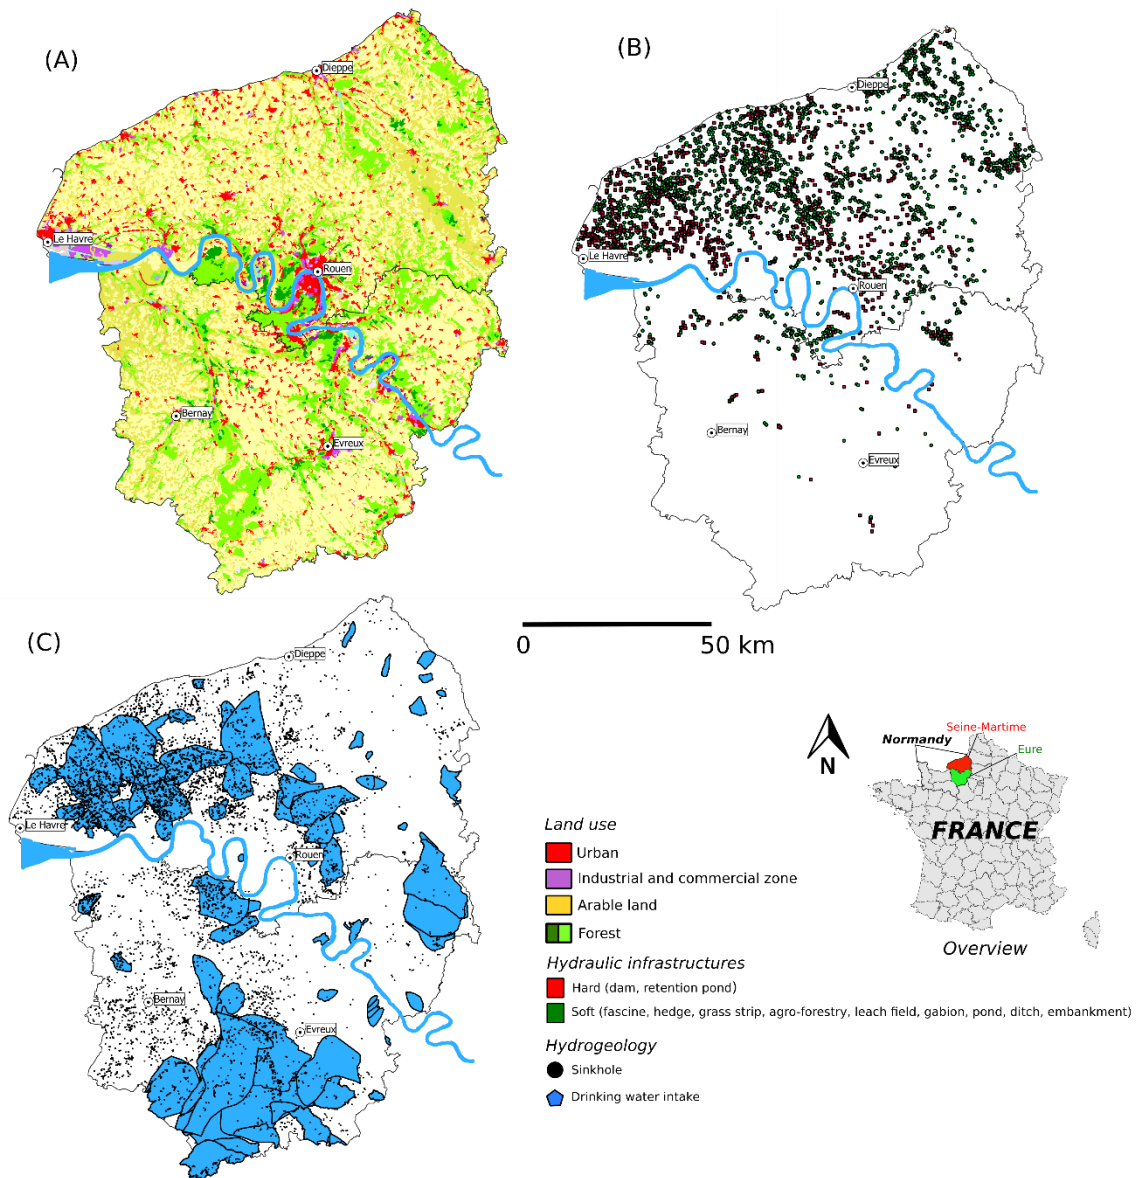

54 accelerated runoff leading to localized flooding, degradation of drinking water (Clark, 1996). Over the
55 past years, much attention has been drawn to on-site costs. In the US, Pimentel et al. (1995) estimated
56 to 27 billion US \$ yr⁻¹ the on-site costs generated by soil erosion. In Europe, Panagos et al. (2018)
57 estimated to 1.25 billion € the cost of crop productivity loss due to soil erosion using direct cost
58 evaluation. In Java, Indonesia, the loss of crop productivity was estimated to 340-406 M\$ yr⁻¹ (Magrath
59 & Arens, 1989). In USA, the loss of nutrient and organic matter ranged from 5M\$ to 20 billion \$ per
60 year (see review of Santos Telles et al., 2011). However, the off-site costs might be substantial and can
61 exceed the on-site costs by a factor 10 even though a large part of the off-site costs cannot be
62 quantified (Görlach et al., 2004). To the best of our knowledge, few attempts had been made to
63 quantify the off-site costs generated by soil erosion and runoff. Pimentel et al. (1995) estimated the
64 off-site costs for the US to be about 17 billion US \$ yr⁻¹. Evans (1996) estimated from local authority
65 data that the external costs of soil erosion to roads and property to be 14 M£ in England and Wales.
66 Pretty et al. (2000) estimated the off-site costs of soil erosion for the UK at 14 M£ in 1996 (range 8-30
67 M£ for 1990-1996). In central Belgium, the societal cost of muddy floods was evaluated to 16-172 M€
68 each year by Evrard et al. (2007). In Aisne (France), muddy floods led to a mean damage of 118 € ha⁻¹
69 yr⁻¹ during a 10-year period (Evrard et al., 2010). In southern England (Brighton and Breaky Bottom),
70 the total cost of erosion and runoff events for insurers in 2000-2001 was estimated to 1.45 M€ (Evrard
71 et al., 2010). Thirty years ago, Holmes (1988) estimated the off-site impact of soil erosion on the water
72 treatment industry to be close to 458-661 M US \$ yr⁻¹. Few studies also tried to evaluate the damage
73 avoidance costs generated by public policy to reduce erosion and runoff impacts. For example, the
74 economic assessment of erosion control measures has been evaluated in the UK through a cost-benefit
75 analysis (Posthumus et al., 2015). It can therefore be seen that economic costs of on-site and off-site
76 impacts of runoff and soil erosion can be very important, but also highly variable. In fact, total
77 economic cost will mostly depend on the societal and biophysical characteristic of the studied
78 environment, and the level of ambition fixed by public policies to reduce the impacts of erosion and
79 runoff on their respective territories. While scientific community attempted to evaluate on-site and

80 off-site costs of soil erosion at global scale (UN FAO, 2019), a detailed study of the economic impact
81 can probably only be done by collecting data obtained by local or regional studies (Dorren et al., 2004).
82 Country like France can be particularly challenging because it presents a wide range of different erosive
83 contexts induced by diversity in soil types, climate, geomorphology, land use, and agricultural systems.
84 In Normandy, runoff and erosion problems have reached an alarming level both in terms of rate and
85 of geographical extent (Souadi et al., 2000; Le Bissonnais et al., 2002; Cerdan et al., 2010). Catastrophic
86 flooding and mudflows still occur regularly and the pollution of drinking water sources by sediments
87 was recurrent in the last decades (Nebbache et al., 2001; Souchère et al., 2003; Evrard et al., 2010;
88 Boardman et al., 2019). Since 2000s, a regional public policy was instituted to reduce soil erosion and
89 runoff impacts (Fullen et al., 2006; Martin et al., 2010). This public policy led to: (i) the construction of
90 hard hydraulic structures (dam, retention pond) to store water runoff, and soft hydraulic structures
91 (fascine, hedge, etc.) to reduce input of sediment by mudflows, (ii) the development of preventive
92 action on the field (animation, technical support), and (iii) the creation of water treatment schemes to
93 reduce turbidity. While the farmer pays on-site impacts of erosion, the off-site impacts are generally
94 financed by local taxes (Martin et al., 2014). The whole public policy deployed in the last decades
95 suggested that a high amount of money had been spent to avoid runoff and erosion impacts on these
96 areas. In parallel, a high financial support was spent due to off-site impacts on public infrastructures
97 (flooding and mudflows on private properties, roads, turbidity at water treatment plant, etc.).
98 Therefore, the purpose of this study was to quantify the main off-site economical costs induced by soil
99 erosion and runoff in two areas sensitives to erosion and runoff and located in the northwestern
100 European loess belt (Seine-Maritime and Eure department, Normandy, France). To reach that point,
101 off-site economic impacts (societal and avoidance damages) of erosion and runoff were evaluated
102 through a global and retrospective analysis of all financial databases available since the last decades
103 (public funders, reinsurance, transport infrastructures, regional health authority, and drinking water
104 companies) and scientific literature review allowing the definition of economic indicators related to
105 runoff and erosion processes.

106 2 Study area

107 The study area is the northeastern part of the Normandy region in France (ex-Upper-
108 Normandy) which is composed of two main departments (Seine-Maritime and Eure; 12 318 km²). The
109 two areas are located in the northwestern European loess belt. The climate is temperate oceanic, and
110 the mean temperature is 11°C with low amplitude oscillations. Even if rain events are rather spread
111 during the year, the mean yearly rainfall shows significant spatial disparities. From 1981 to 2010, the
112 mean yearly rainfall ranges from 503 mm in the southern part of the Eure department to 1 110 mm in
113 the western part of the Seine-Maritime department (SIGES Seine-Normandie, 2013). The geology is
114 composed of the chalk from the Cretaceous period and is overlaid by loamy soils. Altitudes range from
115 0 to 250 m NGF in the southern part of the Eure department. The two departments include 1 420
116 municipalities (745 in Seine-Maritime and 675 in Eure). The area is highly developed, accounting for
117 1 856 221 inhabitants (1 254 378 in Seine-Maritime and 601 843 in Eure; INSEE 2017), 2 126 km of
118 railways, and 29 006 km of roads. In 2015, the GDP per inhabitant was 26 400 €, slightly below the
119 French average (30 600 €) (Eurostat, 2017). Arable land is the most important land use covering 68.8%
120 of the total surface (Fig. 1A). The lithological context explained the predominance of arable lands: the
121 study area is part of the northwestern European loess belt. It is composed of medium-textured soils
122 (silty or loamy soils), recognized for their excellent agronomic performance. Unfortunately, these soils
123 are sensitive to crusting and therefore characterized by high erodibility (Panagos et al., 2014). Rates of
124 soil erosion are low to moderate in this area (0.5-10 t ha⁻¹ yr⁻¹; Cerdan et al., 2010) but a high density
125 of muddy flooding is observed (10-20 km⁻²; Boardman et al., 2019). Flooding and mudflow are the main
126 off-site impacts frequently observed on the territory (Fig. 2). In recent year, a public policy has emerged
127 in Seine-Maritime and Eure department to reduce erosion and runoff impacts (Fullen et al., 2006,
128 Martin et al., 2010). It was mainly driven by the EU Water Framework Directive requiring nations to
129 improve waterways to good “ecological status” (European Parliament, 2000). As illustrated in Figure
130 1B, the public policy led to the building of 1 809 hard hydraulic infrastructures (mainly dam and
131 retention pond with a total water storage capacity of 7 million m³) and 3 000 soft hydraulic

132 infrastructures (fascine, hedge, grass strip, agro-forestry, leach field, gabion, pond, ditch,
 133 embankment). Main off-site impacts observed on the territory are: (i) failure of drinking water supply
 134 due to high level of turbidity, and (ii) damages to buildings and public infrastructures. The high level of
 135 turbidity in drinking water can be mainly explained by a high-density of sinkholes, leading to a rapid
 136 transfer of sediment by runoff and erosion to drinking water intakes (Nebbache et al., 2001; Fig. 1C).

141 **Figure 2: (A) Grumesnil, Seine-Maritime, mudflows, May 2016, and (B) Buchy, Seine-Maritime, flooding, May 2016.**

142 **3 Input data and methods**

143 ***3.1 Transport infrastructures***

144 *3.1 Road network*

145 The data were collected from the departmental road services of the two departments. Data
 146 included economic cost for departmental road only, excluding highway, national and municipal roads.
 147 Departmental roads extend over a linear of 10 941 km. The road network management is divided into
 148 8 agencies and 56 operating centers. The operations following mudflows or floods consist in: (i) the
 149 cleaning of basins, ditches, and pipes, (ii) pavement or hydraulic structures repairs, and (iii) pavement
 150 cleaning. These interventions necessarily induced economic costs that can be carried out either under
 151 contract or subcontracted to companies.

152 *3.2 Railway network*

153 The data were collected from the French railway company “SNCF” who manage the rail
 154 network in the Normandy region. The data provided a financial summary of expenditures incurred on
 155 minor incidents related to floods, mudflows, and landslides from 2012 to 2018. We draw the reader’s
 156 attention to the fact that the data provided by the SNCF does not consider exceptional events
 157 identified and announced by the French meteorological service “MétéoFrance”, which are then
 158 economically charged to a national financial scheme attached to the event. Some infrastructures

159 presenting a high risk of erosion and known to the SNCF require special surveillance. Their staff
160 regularly visit these structures (on a regular, one-off or on-call basis), but the associated economic
161 costs are listed in a specific account and indistinguishable. Finally, mudflows on railway network may
162 be responsible for delays and remedial works but the economic costs are aggregated in a maintenance
163 envelope, which is again indistinguishable.

164 **3.2 Insured assets**

165 In France, since the introduction of the compensation scheme for natural disasters in 1982,
166 the “Caisse Centrale de Réassurance” (CCR) provides access to unlimited state guaranteed reinsurance
167 cover for natural disasters in France to those insurance companies requiring this protection (CCR,
168 2017). In parallel, as the secretary of the Inter-Ministerial Commission for Natural Disasters, CCR
169 maintains a database (CatNat aka “Catastrophe Naturelle”) in which are recorded all decrees
170 recognizing the occurrence of a natural disaster. Over the time, CCR has collected data from insurance
171 companies it reinsures under bilateral agreements to understand better France’s exposure to natural
172 disasters, covering insured risks (by location or communes) and claims incurred. According to the
173 analysis of the French insurance market exposure to floods by CCR, insured flood losses are generally
174 located inside the floodplains (45%), outside the floodplains (45%), and another 10% is due to sea surge
175 flood and groundwater rise (Moncoulon et al., 2014). This database contains up to 60% of market data
176 in terms of claims incurred (71 cedants). In this study, we focus on specific disaster types: flooding and
177 mudflows. For the Seine-Maritime and the Eure departments, the database contains over 1 377 entries
178 starting in 1998. The CCR’s extrapolated claims costs are calculated when claims are loaded. Claims are
179 linked to the CatNat database, ordered by peril and date of occurrence. CCR’s cost extrapolation
180 methodology is as follows: the sum of claims from a cedant is compared to annual accounting data and
181 cost data by events received by CCR. Then for each financial year, the market share of the cedants
182 providing the data is calculated. The number of cases and amount of claims received per fiscal year are
183 extrapolated using an extrapolation coefficient. Thus, for each claim, the following elements are
184 reported: the municipality, the date, the initial cost, the extrapolated cost, the number of extrapolated

185 claims. The natural disaster guarantee provides for the coverage of direct material damage “net of
186 deductibles” caused only to the insured property. Operating losses resulting from direct damage are
187 also covered. However, the database does not consider the cost of damage to uninsured property. To
188 overcome this limit, an assessment of actual damage can be estimated by multiplying the extrapolated
189 cost by 1.5 (CEPRI, 2019, personal communication).

190 **3.3 Supply of drinking water**

191 Turbidity in karstic environment like ex Upper-Normandy is a natural phenomenon linked to
192 operational activities like pumping (Hanin, 2011), resuspension of sediment in karstic storages and
193 conduits (Masséi et al., 2003; Valdes et al., 2005), as well as because of rapid transfer (via sinkholes)
194 on the surface catchment induced by heavy rainfall events (Valdes et al., 2006; El Janyani et al., 2014).
195 Turbidity is a significant challenge to the operation of a drinking water company and can affect its
196 ability to continue to supply potable water (Stevenson and Bravo, 2019). According to the French law
197 and based on the decree 2001 - 1220 of 20 December 2001, operators of water distribution systems
198 must ensure that the water they distribute meets drinking water standards. The limit set out in the
199 drinking water quality is 1 NTU (Nephelometric Turbidity Unit) at the point of distribution. In case of
200 heavy rainfall events, few drinking water suppliers cannot reach that threshold. This may be explained
201 by: (i) a persistence of a high turbidity level (< 12 – 24 h), (ii) a water treatment process not effective
202 enough to filter the turbidity peak, and (iii) a lack of water treatment process or emergency
203 interconnection. When the drinking water quality is not sufficient at the point of distribution, the
204 regional health authority (“Agence Régionale de Santé”; ARS) issues an alert to prohibit the clean water
205 drinking and distributes bottled water to the population (1.5 L/day/capita). The prohibition of clean
206 water drinking induces three main economic costs: (i) bottled water purchase, (ii) information to the
207 public, and (iii) logistic for the distribution. In Seine-Maritime and Eure, 407 prohibitions of clean water
208 drinking were recorded since 1992. The number of inhabitants impacted, and the duration, is known
209 for 60% of the records. For the remaining 40% (exclusively in Seine-Maritime), the duration was missing

210 and evaluated, based on the mean duration of the fully detailed records in this department (10.5 days).
211 The total bottled water purchase (BWP; € exc. tax) is calculated based on the following equation:

$$BWP_{total} = \sum_{i=1}^n BWP_i = \sum_{i=1}^n N_i * \Delta t_i * A * B \quad \text{Eq. 1}$$

212

213 With N_i the number of inhabitants impacted for the record i , Δt_i the duration (in days) of the
214 prohibition alert, A is a constant equal to 1.5 liter, and B is the mean price of a bottled water (0.0986
215 € exc. tax. L⁻¹; bulk purchasing) considering feedback from the “Le Havre Seine Métropole” (LHSM).
216 Based on two fully detailed study cases from LHSM, and ARS (Mansotte, 1998), information and logistic
217 costs were evaluated respectively to 0.648 and 0.74 € exc. tax per inhabitant per record.

218 **3.4 Regional authorities’ financial databases**

219 Between 2000 and 2017, seven public institutions funded the public policy against runoff and
220 erosion impacts: (i) the Seine-Normandie Water Agency (AESN), (ii) the Seine-Maritime department,
221 (iii) the Eure department, (iv) the Haute-Normandie Regional Council (CRHN), (v) the European
222 Regional Development Fund (FEDER), (vi) the French state, and (vii) the parliamentary reservation.
223 Database from the FEDER, the French state, and the parliamentary reservation were not available and,
224 hence, were not analyzed in this study. However, the total costs associated to each project were
225 available in the other databases. By checking the financial monitoring from the four selected
226 institutions, it is possible to determine the total cost of a project, and the portion eligible for public
227 subvention. In the framework of the public policy against erosion and runoff, only eligible amount was
228 kept for further analysis. Unfortunately, funding can be manifold on a given project, as illustrated in
229 Figure S1. To estimate the overall volume of public investment, data were crossed and visually checked
230 to avoid double-counting. We also categorized the investments in nine categories (including different
231 sub-categories). Investments were separated based on two simple objectives, the one specific to
232 erosion and runoff and the other specific to turbidity. Some investments relied to both objectives. For

233 investments specific to erosion and runoff, we used all data provided by the public funders. For
234 investments specific to turbidity in drinking water, the AESN database was sufficient, because on this
235 problematic, it is the AESN that always fund the projects. For the first category (i.e. investments specific
236 to erosion/runoff), AESN's database was used as a reference and redundancies were checked in the
237 three other databases. For the CRHN, only 9.17% of the total investment was not redundant with the
238 AESN database and kept for further analysis. For the Eure department, 131 projects were not co-
239 funded by the AESN and kept for the analysis. For the Seine-department, the redundancy was difficult
240 to evaluate, so two implicit assumptions were made: (i) AESN and Seine-Maritime always co-funded
241 project, so we take the maximum investment of a project from one or another, and (ii) both institutions
242 never co-founded a project and their respective investment can be summed. Cross-validation with data
243 from a local river basin committee ("Syndicat Mixte du Bassin Versant de l'Austreberthe et du
244 Saffimbec") suggested that priority must be given to the second hypothesis. For the second category
245 (i.e. investments specific to turbidity in drinking water) investments were considered carefully. Indeed,
246 actions can have several motivations, and investments can be motivated by a desire to protect drinking
247 water against other types of pollution (nitrates, pesticides, PAHs, etc.). Empirical ratios were defined
248 to extract the part of the overall investment for drinking water specific to the turbidity. Based on expert
249 knowledge and discussion with public funders, we applied the following ratios on three main
250 categories to extract the relative part induced only by turbidity in drinking water: 50% on investments
251 relating to animation on the field; 70% on investments relating to water potabilization and drinking
252 water quantitative management.

253 ***3.5 Erosion control measures and maintenance***

254 The overall erosion control measures against runoff, erosion, and turbidity to drinking water
255 in the Seine-Maritime and Eure department (see details in Fig. 1B), is recorded by the "Association de
256 recherche sur le Ruissellement, l'Erosion et l'Aménagement du Sol" (AREAS) in an open-access
257 database called CASTOR ("Connaissance des Aménagements de préservation des Sols et des Terres, et
258 des Ouvrages de ralentissement des Ruissellements"; <http://bdcastor.fr/>). For the purposes of the

259 study, we extracted from the database all infrastructures located in the studied area ($n = 4\,809$). To
 260 assess the volume of investment related to the maintenance of these infrastructures, a first screening
 261 was necessary. We extracted only functional hydraulic infrastructures that need recurrent
 262 maintenance, and for which the year of construction and the dimensions were given. We discarded
 263 the steel gabions and timber cribs, for which the dimensions were not available, or the annual
 264 maintenance cost could not be determined. The final database that is used to evaluate the economic
 265 cost of hydraulic infrastructures maintenance includes 3 946 entries (Table 1). For each entry, the
 266 maintenance cost was evaluated based on the year of construction, the dimensions, and the annual
 267 maintenance cost. The annual maintenance cost was assessed through literature review and feedbacks
 268 from building owner's projects. The total economic cost of the overall maintenance was assessed
 269 considering inflation. The annual maintenance costs are corrected for inflation based on the analysis
 270 of the evolution of the cost of production indices for public works (ICP-TP) from 1998 to 2018 (deflator
 271 = 100 in 2018; Fig. S1). Between 1998 and 2018, the average annual variation is thus estimated at -
 272 2.1%. This average annual variation was applied to the previous years until 1931 (date of creation of
 273 the oldest dam listed in the BD CASTOR). Annual maintenance cost for each erosion control measures
 274 were then corrected and aggregated over time.

275 **Table 1: Synthesis of existing erosion control measures (number and overall dimensions) on the Seine-Maritime and Eure**
 276 **department, extracted from the Castor database (lm = linear meters).**

	Seine- Maritime	Eure	Seine- Maritime	Eure
Erosion control measure	Number (n)		Dimensions	
Dam/Retention pond	697	76	5 330 133 m ³	209 652 m ³
Leach field	9	1	203 ha	4 ha
Fascine	636	30	18 210 lm	641 lm
Hedge	1 003	30	201 751 lm	4 433 lm
Pond	795	44	1 110 364 m ³	35 007 m ³
Ditch	314	57	88 230 lm	11 246 lm

Grass strip	79	24	64 ha	13 ha

277

278

279 **4 Results and Discussion**

280 **4.1 Off-site avoidance damage cost**

281 *4.1.1 Overall investment*

282 The total investment costs had been evaluated through the analysis of all regional authorities’
283 financial database available since 2000 (Table 2). The analysis suggests that 4 307 projects were
284 financially supported to reduce runoff, erosion, and turbidity impacts on the Eure and Seine-Maritime
285 department. The overall volume of public investments ranged from 300 to 410 M€ exc. tax. between
286 2000 and 2017. According to the upper boundaries (i.e. section 3.4) of the analysis, the AESN and the
287 Seine-Maritime department were the two main public funders with an investment of 276.7 M€ exc.
288 tax. (67.5%) and 117.3 M€ (28.6%) respectively. They supported 2 699 and 1 236 projects, respectively.
289 Between 2003 and 2017, the Eure department invested 8.4 M€ (2.1%) for 70 projects. The CHRN
290 invested 7.6 M€ (1.8%) between 2001 and 2009 for 302 projects. The largest expense is for hard
291 hydraulic infrastructures (i.e. dam and retention pond) with a volume of investment ranging from
292 106.3 to 188.8 M€ exc. tax. This volume of investment mainly includes rehabilitation/building of
293 infrastructures, feasibility studies, and exceptional maintenance (mainly dredging) due to exceptional
294 rainfall events. Total investment for soft hydraulic infrastructures (i.e. fascines, hedges, grass strips,
295 etc.) is much lower and ranged from 25.3 to 27.8 M€ exc. tax. The volume of investment for hydraulic
296 infrastructures for which the type is unspecified counts for 8.2 to 10 M€ exc. tax. The total investment
297 for hydraulic infrastructures reached 226.8 M€ exc. tax., almost 56% of the overall investment.
298 Drinking water equipment, for potabilization and quantitative management, represents a volume of
299 investment of 47.1 and 39.3 M€ exc. tax., or 21% of the overall investment. The Seine-Maritime and
300 Eure department have almost invested the same financial volume, respectively 45 and 40 M€ exc. tax.
301 These categories mainly include water quality monitoring, analysis of water supply and treatment
302 installations, building/rehabilitation of water treatment unit, interconnections, and instrumentation
303 of water treatment unit. Global studies (storm water management schemes, water development and

304 management plan, environmental impact assessment, water legislation dossier, research programs,
305 etc.) and animation (agricultural outreach, water resource management, watershed management,
306 etc.) accounts respectively for 8.5% (25-35 M€ exc. tax.) and 10.3% (M€ 29-42 M€ exc. tax.) of the
307 overall investment. Management of sinkholes and vulnerability to flooding represent a much smaller
308 portion of total expenditure, respectively 11.5-12 M€ (2.9%) and 7.3 M€ exc. tax. (1.8%).

309 **Table 2: Overall volume of investment funded applying public policy against erosion and runoff impacts in Eure and Seine-Maritime department between 2000 and 2017.**

310

311 *4.1.2 Maintenance cost of erosion control measures*

312 Evaluation of annual maintenance cost for erosion control measures was based on literature
313 review (Table 3). The reference values were chosen based on the reliability of the source and the
314 localization of the study. When different sources were available, an average value was defined.
315 Attention had also been paid to the expression units to allow the correspondence with the Castor
316 database. Considering that the field operators seemed to perceive price stability since 2005, we
317 considered in first attempt that our reference values could be expressed in €₂₀₁₈. For fascines, hedges,
318 ditches, and embankments the annual maintenance cost ranged from 1 to 6.5 €₂₀₁₈ exc. tax. lm⁻¹. The
319 maintenance actions are mainly linked to mowing, or trimming/coppicing. The annual maintenance
320 cost for a pond was fixed regardless of the size and set to 230 €₂₀₁₈. This cost referred to mowing action,
321 considering that costs of cleaning and rehabilitating (around 10 k€/pond) were included in the overall
322 public investments in the previous section. The annual maintenance cost for grass strip and leach field
323 were set respectively to 889 and 460 € exc. tax. ha⁻¹. Grass strips are specific, and the maintenance
324 cost consist in financial compensation for the maintenance of the area and crop losses. Finally, annual
325 maintenance costs for dam and retention pond reached 6,880 € unit⁻¹ considering feedbacks from the
326 catchment stakeholders (LHSM). The reference maintenance costs applied to the erosion control
327 measures listed in the two studied departments led to a total maintenance cost of 76 M€₂₀₁₈ exc. tax.
328 (Table 4). The overall maintenance cost was mainly explained by operations on hard erosion control
329 measures, that required costly civil engineering operations (cleaning) and dedicated monitoring teams.
330 This type of infrastructure had been favored during the last twenty years with the aim of reducing the
331 vulnerability to flooding. Hard infrastructures cost reached 66.6 M€₂₀₁₈ exc. tax. since the beginning,
332 or 88.7 % of the volume of the overall maintenance cost. For soft infrastructures, the cumulative 206
333 km of hedge represented the highest maintenance cost, estimated to 2.6 M€₂₀₁₈ exc. tax. (3.45 % of
334 the overall maintenance cost). Even with a low spatial extent, grass strips and leach fields were
335 expensive to maintain with a global cost of 1.9 M€ (2.5 %). Ponds have a high storage capacity (1.1
336 Mm³) for a low maintenance a cost (1.7 M€; 2.3 %). According to the results, we observed that the

337 global annual maintenance cost of erosion control measures in the Seine-Maritime department is
 338 higher by a factor 10 than in the Eure department.

339 **Table 3: Synthesis of annual maintenance costs (€₂₀₁₈ exc. Tax.) for each type of erosion control measure considered in**
 340 **this study.**

Erosion control measure	Maintenance type	Annual maintenance cost (€ ₂₀₁₈ exc. tax.)	Source
Dam/retention pond	Maintenance of parkland, fences, monitoring team, civil engineering	6 880 unit ⁻¹	LHSM, pers. com.
Grass strip	Agri-environment payment: annual loss in gross margin + grass maintenance	889 ha ⁻¹	CA Seine-Maritime (2019)
Fascine	Trimming, weeding, bundle reloading	3 lm ⁻¹	AREAS (2011)
Hedge	Coppicing, trimming, weeding	2 lm ⁻¹	AREAS (2011); LIOSE (2018)
Pond	Mowing	230 unit ⁻¹	Ramaekers (2018)
Embankment	Mowing	6,5 lm ⁻¹	ZH29 (2012)
Ditch	Mowing, dredging	1 lm ⁻¹	CA Hauts-de-France (2018)
Leach field	Mowing	460 ha ⁻¹	CA Hauts-de-France (2018)

344

345 **4.2 Off-site social damage cost**

346 *4.2.1 Insured assets*

347 The off-site social damages associated to flooding, runoff and mudflows were subject to 1 019
348 CatNat decrees between 1998 and 2016 in the two cited departments induced by 65 heavy rainfall
349 events that totalized 21 497 claims. The sum of the initial costs provided by the insurance cedants
350 amount to 44.5 M€ (Fig. 4). Considering the extrapolation of cases and number of claims for each
351 financial year, the sum of the extrapolated costs raised to 150.7 M€. Considering hypothesis for
352 uninsured properties (see section 3.2), the assessment of actual damage reached 226 M€. The
353 temporal evolution of costs showed that most events occurred between 1998 and 2003. In December
354 1999, 505 municipalities experienced disasters in the two departments for a real cost of 53 M€. Spring
355 storms also caused significant damages in May 2000 and June 2003, where 139 municipalities were
356 affected, and a real cost of damages estimated to 35 and 70 M€. For the event of June 2003, the cost
357 for the town of Le Havre alone was estimated to 59 M€ (caused rather by urban runoff). The total costs
358 of damages to individuals were estimated to 153.1 M€ (Table 4). The total cost of damages to
359 companies was lower and reached 72.9 M€ in the two departments. The damages were significantly
360 higher in the Seine-Maritime than in the Eure department, with respectively 195 and 31 M€ in
361 cumulative damage costs. However, we observed that the median real cost to professionals, per
362 CatNat decree or per event, was higher in the Eure than in the Seine-Maritime department. The median
363 cost per municipality, or per year and per municipality, for professionals was roughly equivalent in the
364 two territories. We also observed a greater dispersion of the values over the Seine-Maritime territory.
365 For example, even if the median real cost per event for professionals was lower in Seine-Maritime than
366 in Eure (57.7 against 82.4 k€), the standard deviation was much greater (3.9 M€ compared to 909 k€).
367 The real cost of damages to individuals was generally higher in Seine-Maritime than in the Eure,
368 whatever the indicator chosen, and here too the standard deviation was much higher.

369

370 **Figure 3: Temporal evolution of social damage costs induced by flooding and mudflows and listed by the CCR in the Seine-**
 371 **Maritime and Eure department (1998-2016).**

372 **Table 5: Economic indicators for individuals and companies of social damage costs induced by flooding and mudflows and**
 373 **listed by the CCR in the Seine-Maritime and Eure department (1998-2016).**

	Seine-Maritime		Eure

374

375 *4.2.2 Transport infrastructures*

376 The database provided by the French railway company reported 36 incidents between 2012
 377 and 2018, including 13 mudflows, 4 landslides, and 19 floods. The economical cost supported by the
 378 company and linked to these incidents reached 639 k€ exc. tax (Table 6). The amount of damage per
 379 incident varies widely, from a few hundred euros to 145 k€. There is also high inter-annual variability
 380 with two significant years as 2013 and 2018 with a total cost of damages reaching 303 and 228 k€

381 respectively. Flood-type incidents accounts for 494 k€ exc. tax. over the studied period, followed by
382 landslides (67.5 k€), and mudflows (77.2 k€).

383 Damage costs induced by flooding, mudflow, and landslides to roads were provided by the two
384 departmental road services (Table 6). Data provided by the Eure departmental road service suggested
385 a total damage cost of 1.1 M€ between 2014 and 2020. This cost included the diagnosis and filling of
386 underground cavities, road cleaning and repairs, and the dredging of engineering structures. We
387 observed a significant annual variability with an annual total damage cost ranging from 35 to 316 k€.
388 The mean annual damage cost supported by the Eure departmental road service was estimated to
389 164.8 k€ exc. tax. The total damage cost was higher in the Seine-Maritime for a shorter period and
390 estimated to 3.9 M€ between 2015 and 2018. This cost included the dredging of engineering structures
391 that was subcontracted, road cleaning and repairs. The costs were more constant over time, and the
392 mean annual damage cost supported by the Seine-Maritime departmental road service was estimated
393 to 972k€ exc. tax.

394 These costs remained low at the scale of the studied region (i.e. Upper-Normandy region; 12
395 318 km²). However, it is well known that linear transports networks are very sensitive to runoff hazards
396 in this region (Lagadec et al., 2016b, 2018; Braud et al., 2020) that can directly damage railway track
397 or electric installations, roads, and induced indirect costs such as temporary traffic stoppage. In this
398 study, the economic cost of erosion and runoff on the railway network and departmental road is
399 probably underestimated and highlighted a lack of sufficient and available data.

400
401

402

403 *4.2.3 Supply of drinking water*

404 The evaluation was based on the 407 prohibitions of clean water drinking induced by an
405 excessive turbidity at multiple water treatment plant and recorded in the Eure (n = 88) and Seine-
406 Maritime department (n = 319) between 1992 and 2018. Over the entire period, 1.6 M inhabitants
407 were impacted, and the total damage cost reached 4.7 M€ exc. tax. The cumulated damage cost
408 between 1992 and 2018 reached 3.8 M€ in the Seine-Maritime department and 0.9 M€ in the Eure
409 department. The financial volumes are distributed as follow: distribution of bottled water for 2.5 M€
410 (53.2%); distribution logistics for 1.2 M€ (25.5%); and the public alert management for 1 M€ (21.3%).
411 The mean cost of an event was slightly higher in the Seine-Maritime department (12 k€) than in the
412 Eure department (10 k€). The mean duration of a prohibition of clean water drinking event lasted
413 longer in the Eure department (17.6 days) than in the Seine-Maritime department (10.5 days), but the
414 mean population impacted was lower (2 941 versus 4 147). Despite substantial investments since the
415 last decades to reduce erosion and runoff on the studied areas, we observed that some drinking water
416 companies are still regularly impacted.

417

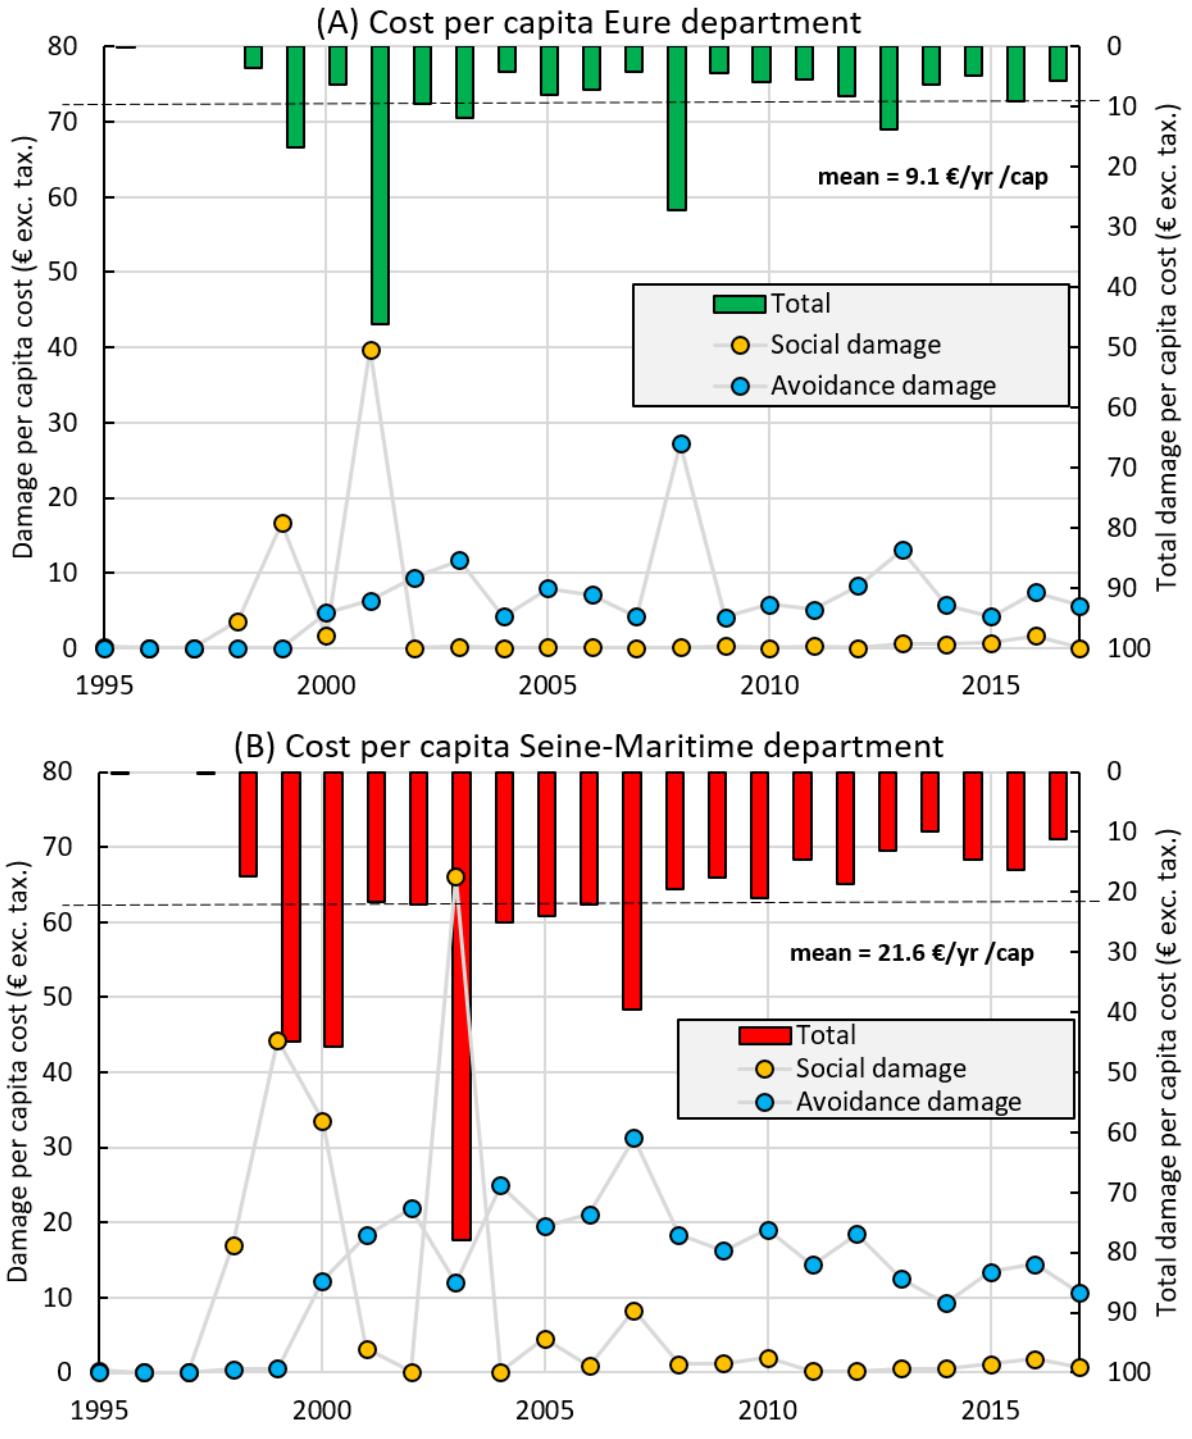

418 **Figure 4: Temporal variability of indirect damage costs induced by turbidity at water treatment plant in the Seine-Maritime**
 419 **and Eure department. The damage costs included the distribution logistic, the bottled water dispensing, and the public**
 420 **alert (SM = Seine-Maritime; E = Eure).**

421 **4.3 Overview**

422 Our analysis suggested that main off-site impacts of erosion and runoff can led to significant
423 expenditures for public authorities. In the two studied areas (i.e. Seine-Maritime and Eure), located in
424 the northwestern European loess belt, the total damage costs induced by the main off-site impacts of
425 erosion and runoff ranged from 611 to 721 M€ over the last 25 years. The Seine-Maritime was the
426 most impacted area and the total damage cost ranged from 494 to 604 M€. In the Eure, the total
427 damage cost reached 116 M€. For both areas, off-site avoidance damage costs represented 65 to 72%
428 of the total financial expenditure and off-site social damage costs represented 28 to 35%. For example,
429 and on average, 1% of the Seine-Maritime's department annual budget was spent each year to reduce
430 erosion and runoff off-site impacts.

431 The projection of these costs over time (1995-2017) in relation to the demography showed us
432 that the mean cost per capita for the Seine-Maritime reached $21.6 \text{ € yr}^{-1} \text{ cap}^{-1}$ and was higher than in
433 the Eure for which it was evaluated to $9.1 \text{ € yr}^{-1} \text{ cap}^{-1}$ (Fig. 6). Even if few erosion and runoff studies
434 focusing on the economical dimension exist (Panagos et al., 2018), we found that some attempts have
435 been proposed in the northwestern European loess belt to quantify the cost of the erosion and runoff
436 off-site impacts. In Flanders in Belgium, Verstraeten et al. (2006) suggested that the cost of erosion
437 off-site impacts reached 55 to 90 M€ yr⁻¹. The studied off-site impacts were damages from muddy
438 floods to private properties, river, and pond sedimentation. In relation to the demography the mean
439 cost per capita can ranged from 9 to $14.8 \text{ € yr}^{-1} \text{ cap}^{-1}$. In Alsace in France, Cerdan et al. (2009) quantified
440 the cost of direct and indirect damages induced by muddy floods on private properties, industries, and
441 communities between 1984 and 2006. The results suggested that the mean cost per capita reached 26
442 $\text{€ yr}^{-1} \text{ cap}^{-1}$. In South Limburg in Netherlands, the mean cost per capita due to erosion off-site impacts
443 reached $1.04 \text{ € yr}^{-1} \text{ cap}^{-1}$ (Van Eck (1995) in Kwaad et al. (2006)). Even if the economic cost of off-site
444 impacts can be different due to the availability of the data, one can observed that these costs remain
445 in the same order of magnitude in the northwestern European loess belt.

446 While these costs are significant, unfortunately they are not exhaustive and represent only the
447 “tip of the iceberg”. In this study, we addressed a detailed and accurate assessment of main off-site
448 costs associated with soil erosion in northwestern France, which could be extrapolated in other areas
449 of the northwestern European loess belt. Soil erosion community could go further using these results
450 and those found in the literature and reported in table 7. But the challenge would be ambitious trying
451 to quantify all existing off-site impacts of erosion and runoff. The quantification of off-site costs in
452 some areas can also be difficult if the data are not centralized. Moreover, there is still different types
453 of off-site impacts for which related costs are still unknown (i.e. psychological damages, loss of value
454 of a flooded habitat, patrimonial values of preserving soils) and more research are therefore required.

455

456

457

Figure 5: Temporal evolution of cost per capita induced by erosion and runoff main off-site impacts for the two studied areas (Seine-Maritime and Eure).

458 Table 7: Example of off-site impacts induced by erosion and runoff and their economic assessment.

Service / function	Soil erosion and runoff impacts	Evaluated in this study?	Evaluated in the literature
Support of food, fuel and fibre production	Reduced crop productivity	No	The annual loss of crop productivity is estimated to be around 1.2 billion € in Europe (Panagos et al., 2018); 3.55 £ per ha (Posthumus et al., 2015)
Drainage/discharge of water	Siltation of dams and watercourses	No	0.85 \$ per ton of sediment (Moore et al., 1987); 1.29\$ per ton of sediment (Macgregor, 1988); 16.62£ per ha (Posthumus et al., 2015)
Infrastructures	Interruption of services, transports	No	Median indirect cost of a hydrometeorological event on the European railway network estimated to 1 M€ (Maurer et al., 2012)
Infrastructures	Damages to road	0.23 – 0.77 € yr ⁻¹ cap ⁻¹ in average	2.65 £ per ha (Posthumus et al., 2015); 14 k€ - 300 k€ per event and per municipality (Evrard et al., 2007)
Infrastructures	Damages to railway	0.02 – 0.07 € yr ⁻¹ cap ⁻¹ in average	Median direct cost of a hydrometeorological event on the European railway network estimated to 1.69 M€ (Maurer et al., 2012)
Infrastructures	Cleaning operations (roads and streets)	No	500 € – 11 k€ per event (Evrard et al., 2007)
Infrastructures	Damages to private properties and companies	3.4 – 9.6 € yr ⁻¹ cap ⁻¹ in average	10 – 30 € ha ⁻¹ yr ⁻¹ at the level of a municipality in Flanders in Belgium (Boardman et al., 2006); 5.5 € ha ⁻¹ yr ⁻¹ for South Limburg in Netherlands (Schouten et al., 1985)
Infrastructures	Fire brigade interventions	No	2.25 k€ – 25 k€ per event (Evrard et al., 2007)
Provision of drinking water	Water treatment cost to remove sediments and pollutants	No	0.32 \$ per ton of sediment delivered (Forster et al., 1987); 5.27£ per ha

			(Posthumus et al., 2015); 2.17€ per kg of sediment (Patault et al., 2020)
Business interruption	Delayed production of goods and services	No	To the best of our knowledge, there was no scientific literature dealing with those items
Mitigation measures	Maintenance of erosion control measures	1 – 4.6 € yr ⁻¹ cap ⁻¹ based on the inventory for 2018	
Mitigation measures	Building of erosion control measures	7.3 – 14 € yr ⁻¹ cap ⁻¹	
Mitigation measures	Animation (agricultural outreach, water resource management, watershed management)		
Mitigation measures	Drinking water equipment and potabilization		
Mitigation measures	Global studies (environmental impact assessment, water legislation dossier, research programs, etc.)		
Mitigation measures	Management of sinkholes		
Mitigation measures	Vulnerability to flooding		
Provision of drinking water	Drinking water prohibition	0.06 – 0.11 € yr ⁻¹ cap ⁻¹ in average	
Health	Human lives lost through floods and mudflows	No	
Health	Anxiety and uncertainty associated with floods and mudflows	No	To the best of our knowledge, there was no scientific literature dealing with those items
Sustainable development	Impact on landscape values and biodiversity	No	
Sustainable development	Patrimonial value of preserving soil for future generations	No	

460 **6 Conclusions**

461 In this study, the main off-site economic costs induced by erosion and runoff processes were
462 assessed for two areas of the northwestern European loess belt located in Normandy in France (Eure
463 and Seine-Maritime areas). We analyzed avoidance and social damage costs over the last 25 years
464 through databases provided by regional and/or local authorities and available scientific literature. The
465 results suggested that between 2000 and 2017 the overall volume of public investments ranged from
466 300 to 410 M€ to avoid erosion and runoff impacts. In addition, 76 M€ were spent for the maintenance
467 of the erosion and runoff control measures. Between 1998 and 2016, 65 heavy rainfall events induced
468 erosion and runoff impacts which led to 21 497 claims to insurances. The total damage costs reached
469 226 M€. Between 2012 and 2018, 36 minor incidents were reported on the railway infrastructures.
470 The economical cost linked to these incidents reached 639 k€. The damage costs supported by the two
471 departmental road services were evaluated to 5 M€ between 2014 and 2020. The prohibition of
472 drinking water in response to high level of turbidity in raw water induced by runoff and erosion led to
473 a significant expense of 4.7 M€ for drinking water suppliers. Finally, we evaluated the total damage
474 off-site costs induced by erosion and runoff impacts to 611-721 M€ over the last 25 years. Thus, the
475 mean cost per capita ranged from 9.1 to 21.6 € yr⁻¹ cap⁻¹ for the Eure and the Seine-Maritime area,
476 respectively. Here we provided a detailed estimation of the annual costs induced by erosion and runoff
477 off-site impacts on the studied areas, which can be extrapolated to other areas in the northwestern
478 European loess belt. However, we are aware that this is a minimum threshold considering that some
479 off-site impacts are still non-evaluable due to a lack of available data or knowledge. We can suggest
480 performing additional research to provide a full picture of all off-site economic costs induced by
481 erosion and runoff impacts.
